INTRODUCTION

Lombalgy is considered one of the musculoskeletal disorders that most frequently affects society, it is also one of the main causes for absence from work, causing permanent disability in the active population (ZAVARIZE, WECHSLER, 2012).

The World Health Association classifies lombalgy as a multifactorial commitment which is the loss or the abnormality of the low back spine, with psychological, physiological, or anatomic etiology, resulting in a disadvantage that figures as an impediment or limitation to physical activities. This perspective brings to evidence the excessive use, compressive or postural syndromes, related to muscular weakness, muscular disorders, fatigue and instability of the trunk (JUNIOR, GOLDENFUM and SIENA, 2010).

According to Zavarize and Wechsler(2012) lombalgy can be classified through many ways, among one of them is the one that considers its duration. The acute lombalgy has a subtle start and lasts up to six weeks, but the subacute lombalgy may last from six to twelve weeks, and the chronic lombalgy persists for more than twelve weeks. It is right to say that the lombalgy classified as chronic is characterized by an incapacitating syndrome and by pain, that persists for more than three months from its start, counting from the first episode of severe pain, and gradual disability, for which the beginning cannot be precised and shows instable periods of aggravation and appeasement.

When an individual is affected by chronic pains, it is of high relevance to exercise, because the practice of physical exercises can decrease the appearing of muscular and musculoskeletal problems, such as shortening, joint mobility loss and weakness, resulting in an increase of pain. The treatment for this pain considers the source of the pain and any deficiencies or functional musculoskeletal limitations, as well as any problem or disorder that may be prevented or identified during the process of evaluation. It has been proven that stretch is very effective in the appeasement of pain and muscular tension (ALMEIDA e JABUR, 2006).

Rodrigues et al (2010) reports that the Pilates method was created in Germany by Joseph Pilates and became popular in New York, after the Second World War. The technique consists in the practice of physical exercises, for which the main characteristics are the resisted tension workout and dynamic stretching, along with the breath focusing on the following points: controlling, precision, centralization, and fluidity of movement, concentration and breath. The most important benefits are improvement of the strength, flexibility, posture and motor abilities. The gain of flexibility and strength of the central muscles of the body, and deep stabilizers (multifide and transverse abdomen), that provide stability for the spine, guarantee static and dynamic body stability, besides favoring balance.

This technique is characterized by movements that keep the spine in neutral position, recruiting only the necessary musculature, avoid premature fatigue and decrease in body stability. The exercises include concentric, eccentric and isometric contractions, with emphasis in the Power House, denominated by Joseph Pilates as the center of strength, composed by abdominal, gluteal, and low back paraspinal muscles, which main functions include to static and dynamically stabilize the body. The method prevents lesions and provides relief for chronic pains, and also stimulates blood circulation, improves physical condition, flexibility and muscular amplitude, posture, motor coordination and levels of body consciousness (ARAÚJO et al, 2010).

Therefore, this study aimed to review the effectiveness of the Pilates method in the treatment of lombalgy.

METHOD

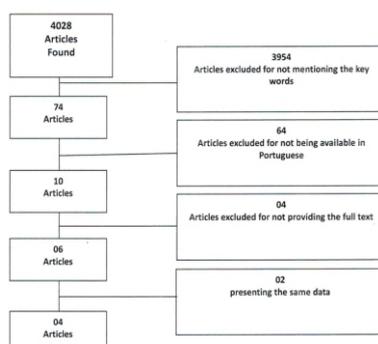

A systematic review on Scielo and Lilacs electronic databases was realized, with texts published in Portuguese, using the following key words: Pilates, lombalgy and effectiveness. Only publications released within the last five years and with full text availability were considered.

Initially every article containing the key words was considered, then the articles published without the period mentioned previously were excluded. Afterwards the articles were filtered by titles, and only those that mentioned the Pilates method as treatment of lombalgy were considered. The search in the database was realized from April to May of 2014, including scientific articles published between 2009 and 2014. After the systematic reading of the selected articles, all the material was compared based on a scientific reading. At last the data were analyzed descriptively by means of graphs and tables.

RESULTS

In this study 3032 articles were initially found in Scielo database and 996 articles were found in Lilacs database. From these, only those that mentioned the Pilates method were selected.

Figure 1 shows the flowchart for the researched articles.

Thus four (4) papers that met the inclusion criteria were evaluated effectively, and these are shown in Figure 2.

ATUHOES	OBJECTIVE	METHOD	RESULTS
Conceição, J. S.; Mergener, C. R. 2012	The objective of the study was to evaluate the effectiveness of the Pilates method in the treatment of chronic lumbalgia	7 female patients diagnosed with lumbalgia and ability to perform Pilates basic exercises were evaluated. Visual analogue scale for pain (VASP) and Oswestry survey were used.	There was significant appeasement of pain, shown by VASp, that initially showed 7 and after 3 months of treatment this number decreased to 1,7. There was improvement in the quality of life with reduction of the Oswestry from 36,8% to 8%.
Silva, A. C. L. G.; Mannrich, G. 2009.	This study aims to evaluate the aspects related to the use of the Pilates method in rehabilitation.	A systematic review in MEDLINE and LILACS databases was realized, using as search term the word Pilates.	The results showed that the Pilates method can be used in different people such as the elderly and pregnant women for different purposes, among them the treatment of lumbalgia regardless of age.
Miyamoto, G. C.; Costa, L. O. P.; Cabral, C. M. N. 2013	Review random controlled studies on the effectiveness of the Pilates method in the treatment of non specific low back pain	Researches in MEDLINE, EMBASE, PEDRO, SCIELO, LILACS, CINAHL and CENTRAL databases were realized in March of 2013	In the metanalysis there was significant difference for pain and disability in the comparison to no other types of intervention or minimum intervention. the Pilates method was not superior to resolve the pain compared to other exercises in the short term.
Marés, G.; Oliveira, K. B.; Piazza, M. C.; Preis, C.; Neto, L. B. 2012.	This study aims to analyze general aspects related to central stabilization on the Pilates method.	Systematic review on the library of the Catholic Pontifical University of Paraná, and also on BIREME, LILACS, PUBMED, CAPES and MEDLINE databases. The research covered publications released between 2000 and 2010.	Central stabilization helps the patient gain strenght, neuromuscular control, muscle strength and resistance, facilitating a balanced muscle function, resulting in an appropriate balance inside the spine and pelvis.

Based on these data, the lack of scientific study reporting the Pilates method as treatment of lumbalgia is evident, as the method gains popularity in the treatment and prevention of musculoskeletal disorders, due to a large number of muscles and articulations exercised in the practice.

For Conceição and Mergener (2012), Pilates has provided stabilization of the low back spine, resulting in a significant appeasement of, improving the results, reducing costs, providing higher achievements in the shorter term when compared to other conventional methods.

According to Miyamoto, Costa e Cabral (2013), exercises of the Pilates method are more effective in reducing pain and disability in the short term, but no definitive conclusion can be made in the medium term interventions. In this study the Pilates method achieved the best results than the other treatments, however difference was not significant, not representing thus a considerable clinical improvement.

Pilates exercises were mostly performed in supine or prone position, resulting in a decrease of the impact in the body sustaining joints, especially the spine. A program of exercises with emphasis in the strenghtening of the extensor muscles of the trunk has shown to be very effective, recovering spine function lumbalgia and quality of life, because Pilates is a method that works with low-impact exercises, strenghtening the abdominal muscles and trunk extensors, providing greater stability to the trunk, treating and preventing lower back pain conditions. This study has proven that within only three months of intervention there was a significant improvement in pain and control of lumbalgia.

According to Silva e Mannrich (2009), Pilates has shown to be an effective tool for physiotherapists in rehabilitation, presenting several benefits, and can be applied from pregnant women to the elderly, in the treatment of orthopedic problems such as lumbalgia. Considering that the incidence of lumbalgia has increased in labor and also recreational activities, the Pilates method has proven to be effective and preventing the appearing of lumbalgia, and also osteoarticular disorders. Pilates central stabilization program was created with the intent of helping individuals gain strenght, balance and muscular resistance, becoming essential for the appropriate load balance inside the spine, pelvis and kinetic chain (MARÉS et al, 2012).

CONCLUSION

Although more research is required, there are scientific evidences that show that the Pilates method has great effectiveness in the treatment and prevention of low back pains, providing improvement in the stabilization, strenght, balance and recovering of the function of lumbar spine.
